Magnetic resonance imaging (MRI) is a medical imaging technique used in radiology to form pictures of the anatomy and the physiological processes of the body in both health and disease. MRI scanners use strong magnetic fields, magnetic field gradients, and radio waves to generate images of the organs in the body. MRI does not involve X-rays or the use of ionizing radiation, which distinguishes ...

The source of the changing magnetic fields in MRI may either be the imaging gradients or radiofrequency (RF) coils. The conductive material in which eddy currents are induced may be any metallic component of the MR scanner (other coils, shields, tubes, and housing), wires or devices within or on the patient, and the patient as a whole (in the final analysis, people are just big bags of saline!)

Why does the RF-field have to be applied at the Larmor frequency for resonance to occur? What is meant by flip angle? Are the individual nuclei still precessing after a 180°-pulse?; Why are all the spins brought into phase with one another after a 90°-pulse? I don't understand why this should happen.

MRI contrast agents are contrast agents used to improve the visibility of internal body structures in magnetic resonance imaging (MRI). The most commonly used compounds for contrast enhancement are gadolinium-based. Such MRI contrast agents shorten the relaxation times of nuclei within body tissues following oral or intravenous administration. In MRI scanners, sections of the body are exposed to ...
